

The Phishing Quiz, Explained Simply

What we built for Step 6, and how it works — no tricky words.

What is this thing we built?

It's a little test with 5 questions about spotting tricky emails. You read a question, pick one answer out of four choices, and press a button to check if you got it right.

Nothing you answer is ever saved or sent anywhere. It's just for you to practice and learn — like a pop quiz at school that doesn't go on your permanent record.

What happens after you answer

No matter what you pick — right or wrong — you always get a little box explaining the answer. That was something you specifically asked for: not just "wrong, try again," but an explanation every single time.

Example: "Which is the bigger red flag?"

✗ **Your answer — "The email is too long"**

✓ **Correct answer — "The domain isn't the real one"**

Underneath: *"Legitimate companies send email from their own real domain, not something that just looks similar."*

If you get it wrong, we don't just tell you "nope" — we also show you which one WAS correct, right there next to your answer. That way you learn the right answer immediately instead of having to guess again.

Keeping score

There's a little counter at the top that goes up every time you get one right, and a progress bar that fills up as you go through the 5 questions. At the very end, you see your total score (like "4 out of 5") and a short message about how you did. There's also a "Try Again" button that wipes the score and starts you back at question 1.

The "robot" that can run any quiz

Here's the clever part: instead of writing brand-new code for every single quiz we ever make, we built one reusable "robot" (we call it the quiz engine) that knows how to run ANY multiple-choice quiz, as long as we give it a list of questions. When we make the next quiz — like one about ransomware — we won't have to rebuild any of this. We'll just hand the same robot a new set of questions, and it'll work exactly the same way, automatically.

A mistake we found — and fixed

Mistake: Only using colors to show right vs. wrong.

At first, we only used color to show which answer was correct (green) and which was wrong (red). But some people can't tell red and green apart very well — colorblindness is actually pretty common. If you only use color, those people can't tell what happened at all. We fixed it by adding little checkmark and X **words** next to the colors — "✓ Correct answer" and "X Your answer" — so everyone can tell what happened, whether or not they can see the colors clearly.

We tested the quiz with a keyboard only (no mouse at all) to make sure someone who can't use a mouse can still play the whole quiz just fine — and they can.
